*Received January 27, 1965*

The effect of the gamma rays from Co<sup>60</sup> on the removal of astringency in Kaki (Oriental persimmons) were observed. The astringency of mature Kaki fruits was removed completely by the irradiation of the gamma rays with dosage more than  $150 \times 10^4$  r. As the radiation dosage increased, firmness and astringency decreased while soluble pectin increased. The fruit of which astringency removed by this treatment became soft like the overripe fruit. The gamma-ray irradiation seems to accelerate the ripening of the fruit. From the data obtained on firmness, and alcohol, acetaldehyde and water soluble pectin contents of the fruit and microscopic observation of its tannin cells after the irradiation, it is concluded that the mechanism of removal of the astringency is the same as in overripe fruits.

## INTRODUCTION

It is well known that there are two types of astringency in Kaki (Oriental persimmons): astringent and non-astringent. The non-astringent type of the fruit becomes non-astringent to the taste as it comes to maturity on the tree, while in the other type the fruit remains astringent until it becomes overripe. In our country the astringent Kaki is generally made edible by removing its astringency using some artificial treatments. On the removal of astringency of Kaki, several workers have published their studies. Kakeshita<sup>1)</sup> has reported that the astringency disappears when the astringent substance is polymerized by acetaldehyde formed in the fruit as it matures. Kitagawa<sup>2)</sup> has observed some difference between the tannin cells of both types in cell wall thickness, pit development and pectin contents, and pointed out a role of pectin in removal of the astringency. He has also found interesting facts that in the artificially treated fruit the astringent substance remains unchanged chemically before and after such treatments and the destruction of the astringency is found to be due to coagulation of pectin which makes the astringent substance insoluble in water. According to McArdle and Neheias<sup>3)</sup>, and Miura, and Mizuta<sup>4)</sup> the treatments by gamma-ray irradiation for the fruits such as apples and oranges increase water soluble pectin in them.

The present work has been attempted to examine further the effect of the gamma-ray irradiation on the removal of astringency using astringent Kaki fruit

\*The report on this study has also been published in Proc. Amer. Soc. Hort. Sci., 84, 213 (1964).

and to clarify the mechanism of removal of the astringency.

## MATERIALS AND METHODS

As the samples to be examined well matured Kaki fruit of the variety Hiratanenashi from our University Orchard were used. For each run of irradiation a couple of the fruits were irradiated in the  $\text{Co}^{60}$  gamma-ray facility of the Institute for Chemical Research, Kyoto University. The treatments were repeated three times. The dose rate in the irradiation chamber was about  $136 \times 10^4 \text{ r/hr}$  when we used the facility. After the irradiation of the fruits, firmness was first measured by a hardness meter. Then the fruits were peeled and the juice was extracted by a juicer. Removal of the astringency was judged by tasting. The astringent substance in the juice was determined by titration with 0.1 N  $\text{KMnO}_4$ , alcohol, acetaldehyde and water soluble pectin contents in the juice were determined using by the colorimetric method<sup>5)</sup>, Ripper's method<sup>5)</sup> and calcium pectate method<sup>6)</sup>, respectively.

## RESULTS

**Removal of the astringency.** The dosage of  $\text{Co}^{60}$  gamma rays used for removal of the astringency in Kaki fruits were 0,  $1 \times 10^4$ ,  $10 \times 10^4$ ,  $100 \times 10^4$ ,  $200 \times 10^4$ , and  $300 \times 10^4 \text{ r}$ . The dose of the gamma radiation less than  $10 \times 10^4 \text{ r}$  did not show any effect on astringency or on the appearance of the fruit. The fruits exposed to the dosage more than  $100 \times 10^4 \text{ r}$  lost the astringency considerably. The ones exposed to  $200 \times 10^4 \text{ r}$  and  $300 \times 10^4 \text{ r}$  lost their astringency completely, but they became soft and the color became slightly dark. The effects of gamma rays observed are summarized in Table 1.

With an aim to clarify the mechanism of the removal of the astringency we observed the firmness, astringency, alcohol, acetaldehyde and water soluble pectin contents of the irradiated fruits exposed to the gamma radiation of various values of dosage. The effects observed are given in Table 2. For comparison, data on the fruits treated with alcohol and hot water are also presented in the table.

As the radiation increased, the astringency decreased. The fruit exposed to  $150 \times 10^4 \text{ r}$  or more tastes non-astringent. Firmness of the fruit decreases almost constantly as the radiation dosage increases. On the other hand, water soluble

Table. 1. Effects of gamma radiation on the removal of astringency in Kaki (Variety : Hiratanenashi).

| Radiation dosage        | Astringency judged by tasting | Appearance of the fruits |
|-------------------------|-------------------------------|--------------------------|
| 0 × r                   | Quite astringent              | No change                |
| 1 × 10 <sup>4</sup> r   | Quite astringent              | No change                |
| 10 × 10 <sup>4</sup> r  | Quite astringent              | No change                |
| 100 × 10 <sup>4</sup> r | Slightly astringent           | Slightly soft            |
| 200 × 10 <sup>4</sup> r | Non-astringent                | Soft, slightly dark      |
| 300 × 10 <sup>4</sup> r | Non-astringent                | Soft, slightly dark      |

pectin contents increases. Alcohol and acetaldehyde contents show a tendency to increase as irradiation increases. It is noted that in the fruit exposed to  $150 \times 10^4$  r the alcohol and acetaldehyde contents are several times lower than in that treated with alcohol or hot water.

**Microscopic observation.** In order to examine the mechanism of the removal of the astringency from the other standpoint, tannin cells of the fruit treated by gamma rays of  $150 \times 10^4$  r were observed microscopically.

Protoplasm in the tannin cells of the irradiated fruits do not coagulate even though the fruit tastes non-astringent. However, it coagulates at once when plasmolysis of the tannin cell occurs or the cell is ruptured, as shown in Fig. 1. Moreover, all the fruit cells are macerated by the radiation and the plasmolysis occurs readily. These observations are similar to those on the tannin cells of overripe fruits.<sup>2)</sup>

## DISCUSSION

The gamma radiation of more than  $150 \times 10^4$  r removed the astringency from astringent Kaki fruit, but the irradiated fruit became soft like overripe fruit. As the radiation dosage increased firmness of the fruit decreased and water soluble pectin contents increased. These changes were similar to those observed by McArdle and Neheias<sup>3)</sup> with apples and carrots. They concluded that these changes were due to depolymerization of the pectic substance by gamma-ray irradiation.

It is well known that ethylene promotes the fruit ripening. This fact has been known to be due to depolymerization of the pectic substance.<sup>7)</sup> Overholser<sup>8)</sup> has reported that exposure of Kaki fruits to dilute concentrations of ethylene and its derivatives for periods of 15 to 25 hours results in a more rapid loss of astringency than for check specimens. The treated fruit, however, tended to soften so rapidly that he concluded this method for removal of astringency being of value only in preparation for local markets. He did not determine the changes in pectin in the fruit, nor did he observe the tannin cells involved microscopically. It seems that gamma rays and ethylene have a similar effect to ripen the fruit rapidly. From these facts mentioned above, as a practical method for removal of the astringency gamma radiation is not very favorable unless any method can be found to keep the irradiated fruit firm.

In the astringent Kaki removal of the astringency by artificial treatment is due to coagulation of protoplasm in its tannin cells.<sup>2)</sup> It is also known that when the astringent fruit becomes overripe the water soluble pectin increases.<sup>3)</sup> Taking into consideration the data obtained on firmness, alcohol, acetaldehyde and water soluble pectin contents, the mechanism of removal of the astringency by the gamma-ray irradiation seems to be different from other artificially treated fruits but is the same as in overripe fruits. This was also confirmed by the microscopic observation.

## ACKNOWLEDGMENT

The author wishes to express his appreciation to Professor A. Kobayashi of Kyoto University and Dr. Clore of the Washington State University for their valuable advice in writing this paper. He is also indebted to Mr. R. Katano, Institute for Chemical Research, Kyoto University, for his kind co-operation with the irradiation of gamma rays.
